**THE BODY IS THE PLACE
WHERE EMOTIONS TAKE
SHAPE.**

2057 sats \ 7 comments \ [@Tef](#) 4 Jul HealthAndFitness

The Body Speaks the Language of Emotions

Anger tends to contract the muscles and increase the activation of the organism, someone may do hours of yoga, but if they do not recognize their anger, they will continue to have a contracted body and an organism that does not calm down.

Sadness can weigh down the posture of the body, lower energy and slow movement, someone may attend all the motivational courses in the world and repeat mantras endlessly, but if they do not recognize their sadness, they will always fall into sluggishness.

Anxiety is often accompanied by shallow breathing and constant tension, someone may practice and discipline themselves to act continuously, but if they do not recognize and accept that they are afraid of being afraid, things will never go the way they want.

Only when low vibration emotions are seen for what they are, accepted and channeled can they make room for emotions such as calmness and joy, which help the body relax, breathe more freely and move with more naturalness.

A person who manages to recognize, accept and channel their own emotions usually also has a freer and more agile body. Because the freedom of the body does not begin in the muscles, it manifests there; freedom begins in the emotions.

If we work only to release physical tension, while continuing to produce the same inner conflicts, we create a vicious circle that feeds itself. The source remains untouched and the body continues to speak the language of emotions that the mind has not yet managed to hear.

Emotions are the alchemical laboratory where human experience is transformed into consciousness; there the breath takes form in the soul and the soul finds expression in the body. When they are accepted, understood and transformed, a person becomes lighter, freer and more authentic.

It is precisely here that the origin of art also lies. Art was not born as an ornament of life, but as a need to process what a person could no longer keep only inside themselves. Song, poetry, painting, dance and theater are languages of the soul, ways to transform emotion into creation. In this process, what could have been a burden for the body became beauty, meaning and freedom.

This is the deepest function of art: to transform emotion into consciousness, the soul into expression and the body from a carrier of the weight of unexpressed emotions into a free instrument of creation.

ON THE LACK OF REPLAY PROTECTION

5549 sats \ 19 comments \ [@Murch](#) 7 Jul bitcoin
bitcoin_beginners

I hadn't blogged in a while, but today I hammered together a few thoughts on BIP110's lack of replay protection.

What is happening?

Around August 8th, 2026 at block height 961,632, BIP110: Reduced Data Temporary Softfork (RDTs) nodes are going to start enforcing mandatory signaling for their unpopular softfork. As RDTs is supported by less than one percent of the hashrate, Bitcoin miners will likely find dozens of blocks before an RDTs miner finds the first signaling block. RDTs nodes will reject the first non-signaling block which will cause a blockchain fork as they relegate themselves to a stunted chaintip extending about one block per day.

Simulation of a fork scenario with [OrangeSurf's Fork Simulator](#)

Meanwhile, the Bitcoin network will hum on with blocks expected just seconds slower than every ten minutes. While Bitcoin nodes would accept the chaintip with RDTs rules, the chain started by the first non-signaling block will have pulled ahead dozens of blocks by the time RDTs finds its first block.

Hope for an airdrop

While there is broad rejection of an intolerant minority trying to impose new rules on the Bitcoin network, some are hoping for the

split to settle into a forkcoin being spun out of Bitcoin. So far, RDTs support has been so low that there might not be a market for selling such an airdrop, but beyond that, any hope to sell would require being able to independently move coins on the two chaintips.

Replay Attacks

While RDTs would introduce several new consensus rules upon activation, during mandatory signaling only blocks are restricted compared to Bitcoin. Transactions sent to either Bitcoin or RDTs will be acceptable to the other chaintip—and we have seen in previous forks that transactions get relayed between node populations in such splits—unless at least one of the inputs of the transaction has been spent on the other chaintip previously. In previous splits (e.g., Bitcoin Cash forking off), Bitcoin services would temporarily suspend service to allow the dust to settle, but this is not expected this time due to RDTs having vanishing support. Either way, users that are interested in preserving their coins on both chaintips should be aware that any transaction made on either chaintip would likely result in funds on both chaintips being moved unless they take special precautions.

I had not heard of this conflicting fee method for splitting coins before, very smart. I'll do that after the chain split and merge the coins into Wasabi's coinjoin pool so other people can passively inherit replay protection.

125 sats \ 0 replies \ [@Murch](#) OP 7 Jul

Thanks, to my knowledge, I might have proposed it for the first time in this context of RDTs.

IS IT TIME FOR THE HERETICS BIP REPO YET?

1411 sats \ 39 comments \ @Scoresby 7 Jul
bitcoin bitdevs

How can we talk about improving Bitcoin if we don't want to talk to each other?

Here is an interesting debate that highlights an interesting aspect of Bitcoin development. Luke Dashjr recently reposted a gist authored by Chris Guida. The gist argues that certain elements of BIP 54 - [#1428059](#) - are misguided.

In response, one of BIP 54's authors, Antoine Poinot, wrote an [X article](#). There are a number of interesting points about how Bitcoin works that you can pick up from reading Poinot's article, but what I found most interesting is the way this debate is playing out.

Where does Bitcoin development discussion take place?

Poinot says that Dashjr has blocked him on X. Dashjr says that the Bitcoin Mailing List is censoring him:

When it comes to *discussing* changes to Bitcoin block validation rules -- the rules on which we must all agree in order to stay in sync -- it is very difficult to avoid centralization.

In theory, every developer with an idea could publish their BIP on their own blog, but having any kind of discussion about things seems like it would benefit from some centralization -- one could imagine some very tedious repetition if discussion was too fractured.

But if there is only once place where discussion takes place, even the normal course of moderation will likely lead to people feeling like they are being unfairly shut out of the conversation. It is the nature of moderating a discussion forum or mailing list that human judgment will be used. This always eventually leads to tough calls.

Can competition solve this problem?

Bitcoin doesn't just have one venue, though: BIPs are proposed on the Bitcoin Development Mailing List and on the BIPs repo and on delving. As far as I am aware, these venues are all moderated by different people.

One might allege that even though all these various venues for discussion are moderated by different people, the moderators are all on the same "side." I imagine Bitcoin could sustain a heretics BIP repo or discussion forum (ie a fourth venue), and indeed this came up when the Ordinals BIP was closed after some years - [#1455710](#).

But I don't imagine it would actually do much to make people feel less frustrated. It seems to me that the problem exhibited in the above example is not a problem of forum moderation so much as tribalism. Once battlelines are drawn, every decision by a moderator is seen to be for one side or the other. The problem really only goes away when discussion is segregated to separate venues for each team...which gets us right back to where we started with people not talking to each other.

I still like the idea of a heretics BIP rep, just because it is cool.

HOW BITCOIN'S PRIVACY WAS UPGRADED

top post

25.1k sats \ 4 comments \ @Kruw
7 Jul math bitcoin privacy

When Bitcoin launched, cypherpunks were keenly aware of its scaling and privacy limitations. The whitepaper covers privacy in section 10 and mentions that generating a new address for each transaction is the minimal first step. It further explains how this precaution is undermined when multiple inputs are spent together in the same transaction (known as the common input ownership heuristic). Additionally, if the value of the sender's inputs is greater than the value of the payment, the recipient can track future transactions made by the same sender (since they must create a *change output* to store their leftover BTC).

Examples... <linked online>

Bitcoiners did not give up on this challenge and raised a bounty to incentivize development for privacy enhancing transactions called coinjoins.

A coinjoin contains inputs and outputs from multiple users and leverages *partially signed Bitcoin transactions* (PSBT) to prevent participants from stealing from each other. However, the naive approach of aggregating payments does not guarantee privacy, since the values of inputs and outputs may reveal the flow of funds for each user within the coinjoin transaction.

To solve this problem, coinjoin protocols were designed so that participants create outputs that match each other. Even though the amounts are visible, each equal value output could belong to any participant.

Unfortunately, this example transaction is not a practical representation of how users behave in the real world: It would be a miracle if all participants started with equal sized inputs instead of arbitrary amounts. If a user has inputs that are smaller than the coinjoin's equal value output, they will reveal common input ownership. If a user has an input that is larger than the coinjoin's equal value output, they will

create change. Here is an example of a real coinjoin using the ZeroLink protocol, which was introduced in Wasabi Wallet 1.0.

All 11 participants received an anonymous output for 0.02013500 BTC. Bob and Charlie each revealed common input ownership. Bob, Dave, Frank, Gary, and Karl each created a "toxic" change output that can be attributed to their inputs.

This is a significant first step since participants are able to create a private output that they can spend in a later payment. However, this path ultimately leads to a dead end: Change outputs created from postmix payments will not have a high enough value to be coinjoined again.

Wasabi Wallet 2.0 introduced the WabiSabi coinjoin protocol, which eliminates the limitation of fixed output sizes. This allows users to consolidate inputs privately within coinjoin transactions and avoid leaving behind any "toxic" change outputs.

The privacy calculation becomes double sided, and computing the number of possibilities reaches impossibility as the size of the coinjoin grows.

This flexibility enables end to end privacy for every payment. Mission accomplished.

Some critics are not satisfied with

this math, because human behavior leaks additional metadata that is difficult to measure. This concern is not unfounded, as there are many transaction fingerprints that can cause an individual to stand out in the crowd. When coinjoin outputs are spent, here's what an observer is able to measure:

- The fee rate of the transaction
- The age of the inputs
- The number of inputs consolidated (and the coinjoin txs they originated from)
- The value of the sender's change output (and the coinjoin tx it gets remixed in)
- Locktime, version, and RBF flag

Wasabi Wallet 2.8.0 eliminates these remaining concerns: If you are spending your coins, why not make the payment inside a coinjoin? A receiver of a coinjoin payment has no starting point to attack from.

- The fee rate is chosen by the coordinator
- The age of the sender's inputs is now an upper & lower bound instead of an exact timestamp
- The number of inputs consolidated and their origin txs are hidden
- The receiver does not learn how much leftover change the sender has, or its output address
- Locktime, version, and RBF flag are the same for all participants
- The sender can batch multiple payments in a single transaction without revealing a common origin

In addition to the privacy gains, payments in coinjoin use less block space so users can also save on fees. Input anonymization, spending, and change anonymization all happens in a single transaction instead of three. This saves ~750 vbytes for a single payment, reducing fees by 55%.

BULL BITCOIN IS OFFICIALLY OPENING THE FIRST LEGAL FRONT AGAINST DAC8 IN EUROPE

14.6k sats \ 10 comments \ @BullBitcoin_ 8 Jul bitcoin

In Europe, DAC8 has turned "Know Your Customer" into "Kill Your Customer."

Today, Bull Bitcoin is officially opening the first legal front against DAC8.

We have brought a case before France's Conseil d'État, the country's highest administrative court, to strike down the decree implementing DAC8 in French law.

Since January 1, 2026, DAC8 has required crypto-asset service providers to systematically collect user and transaction data and subsequently report it to national tax authorities.

These authorities will automatically exchange this information across the European Union and with tax administrations in other participating countries around the world.

The result is a massive international financial-data honeypot linking

people's legal identities, home addresses and crypto activity, including information with no relevance whatsoever to taxation.

DAC8.COM

DAC8: A Global Crypto Honeypot

Mass reporting puts millions of private crypto users and their families at risk.

BULLBITCOIN.COM

This is grossly disproportionate and poses a serious threat to the physical safety of crypto holders and their families.

Until now, most customer data remained within each crypto-asset service provider unless a suspicious transaction was reported or a competent authority made a lawful request.

DAC8 replaces this model with the systematic reporting and cross-border sharing of highly sensitive financial information.

The more authorities, civil servants, contractors, systems and foreign jurisdictions that have access to this data, the greater the risk that it will eventually be leaked, stolen, illegally accessed or sold to criminal organizations. At the same time, kidnappings and violent attacks against crypto holders and their families are rising, with leaked personal and financial data increasingly being used to identify and target victims.

France has already suffered numerous breaches of highly sensitive government and financial databases.

Given enough time, a database of this scale is almost certain to be breached.

When that happens, criminal organizations will gain a ready-made map of who to target and where to find them.

Physical attacks on cryptocurrency holders

Documented physical coercion cases involving crypto holders, traders, and businesses (2014-2026 projection)

This is not responsible financial oversight. It is a recipe for disaster

We filed our initial application before the Conseil d'État on February 24, 2026, followed by a substantive legal brief setting out the full grounds of our case.

This is not a symbolic gesture. It is a serious legal action, grounded in law and handled by experienced legal professionals.

We are seeking the outright annulment of the French decree implementing DAC8's crypto-asset reporting regime, on the grounds that automated mass financial-data collection violates fundamental human rights.

If necessary, we are prepared to take this fight before the Court of Justice of the European Union and the French Constitutional Council.

A victory in France could establish an important judicial precedent and provide a blueprint for other European actors seeking to fight DAC8 in their own countries.

Someone has to draw a line in the sand.

Bull Bitcoin is willing to do it.

Alongside this legal challenge, we are launching: **DAC8.COM**

A complete, fully sourced resource for citizens, journalists and policymakers.

JOIN THE FIGHT. Read it, share it.

There's a curious thing
about Bitcoin that not many
people know.

Buried in block 138,725 of
the blockchain, among
transaction data and code, is
an obituary. Someone
deliberately placed it there, so
that it would be forever
etched in every node of the
network. So that as long as
Bitcoin exists, this tribute will
exist too.

It's a tribute to Len Sassaman.

The first time I read that, I
paused for a moment. Because
it's no small thing. The Bitcoin
blockchain is immutable by
design: what goes in, doesn't
go out. Whoever did that
chose the most permanent
place in the crypto ecosystem
to tell the world that this man
mattered.

That's what led me to spend
several days investigating
who he really was. What I
found was a life that can
hardly be summarized.

I'm going to try anyway.

Leonard Harris Sassaman was born
on April 9, 1980, in Pottstown,
Pennsylvania. He grew up in a
quiet environment, was diagnosed
with depression as a teenager, and
from a young age developed an
obsession with understanding how
systems worked: computers,
networks, the protocols that make
the internet what it is.

He didn't finish a conventional
university degree. What he did was
something rarer and, I think, more
interesting: he went straight into
the real work.

At 18, he was already part of the
Internet Engineering Task Force,
the group responsible for the
TCP/IP protocols that are literally
the backbone of the internet.
Eighteen years old. While most
people that age are trying to figure
out what to study, Len was already
at the tables where decisions were
being made about how the global
network would work.

That says a lot about who he was.

< continue the story online >
